About Me (Using AI Chat)

- Carlos Jaime Barrios Hernandez is a computer science professor and researcher in the field of high-performance computing and large-scale architectures. He is a director of the High Performance and Scientific computing Center (SC3UIS) at Universidad Industrial de Santander (UIS). He has co-founded and organized the Latin American Conference of High-Performance Computing (CARLA) and the Supercomputing and Distributed Systems Camping School (SCCAMP). Today, he is the general chair of the Advanced Computing System for Latin America and Caribe (SCALAC) and part of the board of international collaborations in advanced computing, mainly in HPC and Advanced Computing. He has published research papers on advanced computing, new trends in computing, and parallelism. He was a former DJ in France. Follow social networks. Carlos Jaime is a freeride snowboarder.

- Carlos J. Barrios is doctor in informatics at the Université Côte d'Azur, master in applied mathematics and informatics at the Université de Grenoble, both in France, and systems engineer at the Universidad Industrial de Santander in Bucaramanga, Colombia.

Open Question 1: How to exploit better parallelism to support computing and visualization (AI and Simulation)?

Production visualization: "Pure Parallelism"

From: Hank Childs

Lawrence Berkeley Lab & UC Davis

Production visualization with "pure parallelism": same problems that processing

Pure parallelism emphasizes I/O and memory

      High Cost (Efficiency, Performance, Energy)

      Difficult to programming and use

Hardware Disruption

      Accelerators (GPUs, ARM, Xeon Phi)

      Specific Issues (i.e. TPUs, 3D Memory)

In Situ Strategies:

In Situ Strategy	Description	Negative Aspects
Loosely coupled	Visualization and analysis run on concurrent resources and access data over network	1) Data movement costs 2) Requires separate resources
Tightly coupled	Visualization and analysis have direct access to memory of simulation code	1) Very memory constrained 2) Large potential impact (performance, crashes)
Hybrid	Data is reduced in a tightly coupled setting and sent to a concurrent resource	1) Complex 2) Shares negative aspects (to a lesser extent) of others

Loosely Coupled

- I/O layer stages data into secondary memory buffers, possibly on other compute nodes

- Visualization applications access the buffers and obtain data

- Separates visualization processing from simulation processing

- Copies and moves data

Simulation

data

I/O Layer

Possible network boundary

Memory buffer

read

Visualization tool

Demands Dynamic Memory

Lawrence Livermore National Laboratory

This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.
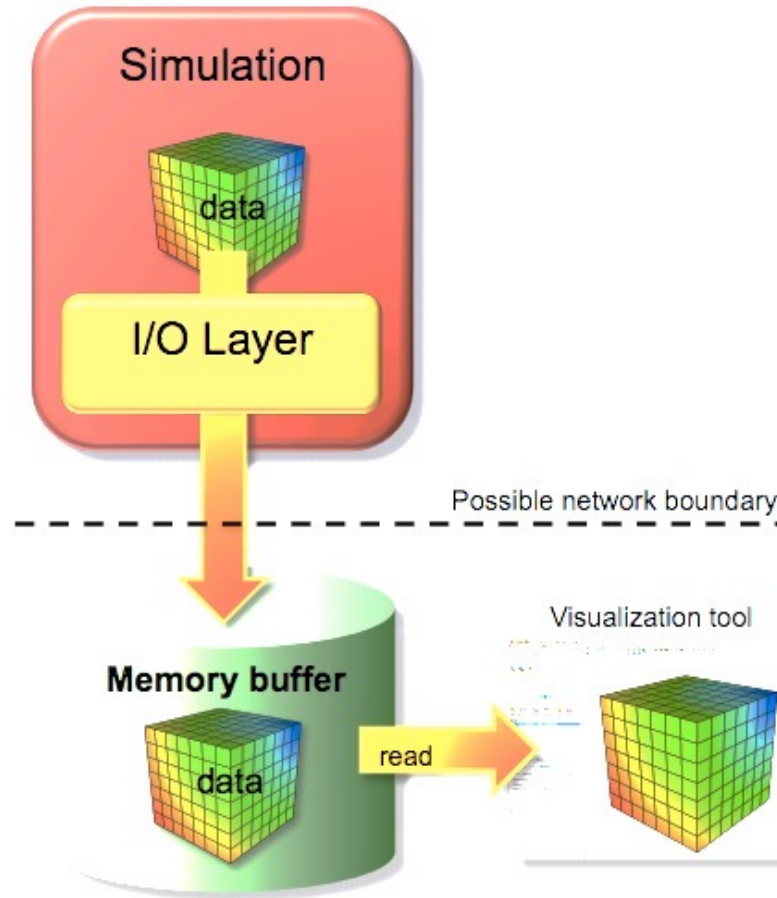

Thightly Coupled

- Custom visualization routines are developed specifically for the simulation and are called as subroutines
  - Create best visual representation
  - Optimized for data layout
- Tendency to concentrate on very specific visualization scenarios
- *Write once, use once*
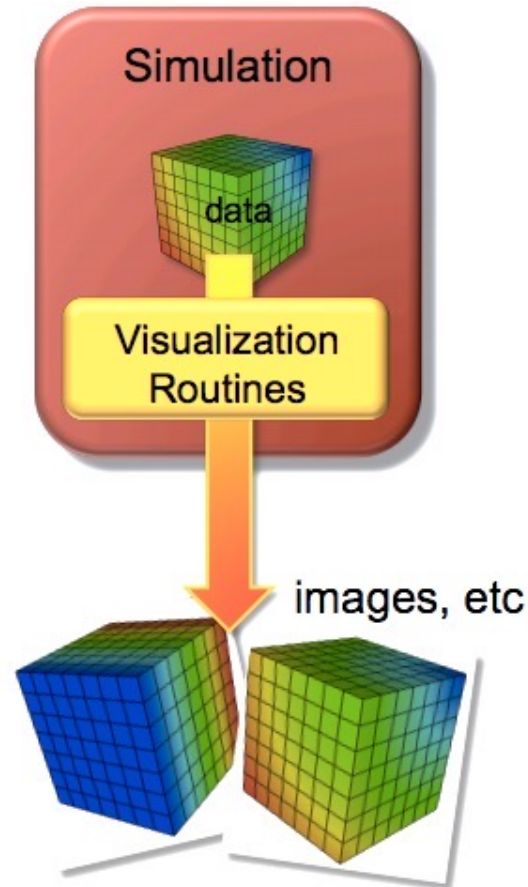

Demands Dynamic Memory and a large amount of memory capabilities

Lawrence Livermore National Laboratory

This work performed under the auspices of the U.S. Department of Energy by Lawrence Livermore National Laboratory under Contract DE-AC52-07NA27344.

Hybrid

- Simulation uses data adapter layer to make data suitable for general purpose visualization library

- Rich feature set can be called by the simulation

- Operate directly on the simulation's data arrays when possible

- *Write once, use many times*
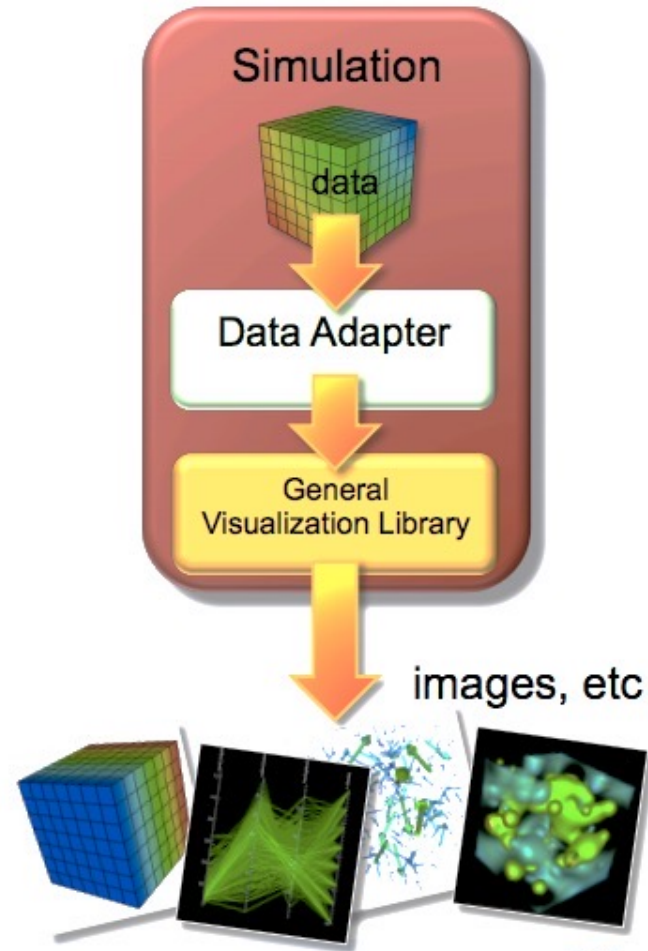

Demands Dynamic Memory, a large amount of memory capabilities and specific algorithm approach

And In Transit?

Analysis and Visualization is run on I/O nodes that receive the full simulation results but write information from analysis or provide run-time visualization

Open Question 3: How to Achieve Efficiency and Scalability in HPC Architectures that Support AI and Big Data?

Two Approach to Contribute to Deal with the Question:

- **Computing Architectural Approach**
- **Algorithm Approach**

COMPUTING ARCHITECTURAL APPROACH

What is the <mark style="background-color:red;color:yellow">problem</mark>?

The need to have increasingly efficient computational resources with better performance, among which are greater processing capacity and memory available for the execution of the training of these models..

→

The deep learning model training algorithm requires a significant amount of memory that often exceeds the capabilities of the GPU and, in some cases, even the memory of the CPU.

New methods for training the model have been created to solve this problem, such as **Model Parallelism**, **Data Parallelism**, and **Pipeline Parallelism**. However, these methods have required increasingly specialized hardware that does not necessarily reduce the memory footprint, but distributes memory requirements across devices such as servers, GPUs, and TPUs.

Is it possible to optimize memory usage in training deep neural network models by distributing or parallelizing the Pipeline between the CPU and the GPU/TPU?

By distributing the Pipeline between the CPU and the GPU/TPU, can better results be obtained in training times while maintaining the accuracy of the model prediction?

By having greater storage capacities in the CPU memory to use it as an active actor, is it possible to increase the size of the input batch and thus improve the efficiency of the training?

Does using the CPU and GPU/TPU simultaneously during training involve more or less energy expenditure when comparing training time Vs. Accuracy Vs. Power Consumption?

Important Aspects:

- Complexity of deep learning models.
- Optimization of the search for hyperparameters in large-scale architectures.
- Population based training
- Generalized DL models
- Evolutionary algorithms in PBT
- Minimizing memory size in the produced model.
- Using AI to bring world-class specialist expertise to everyones, at lower cost.
- Expert care, anywhere.
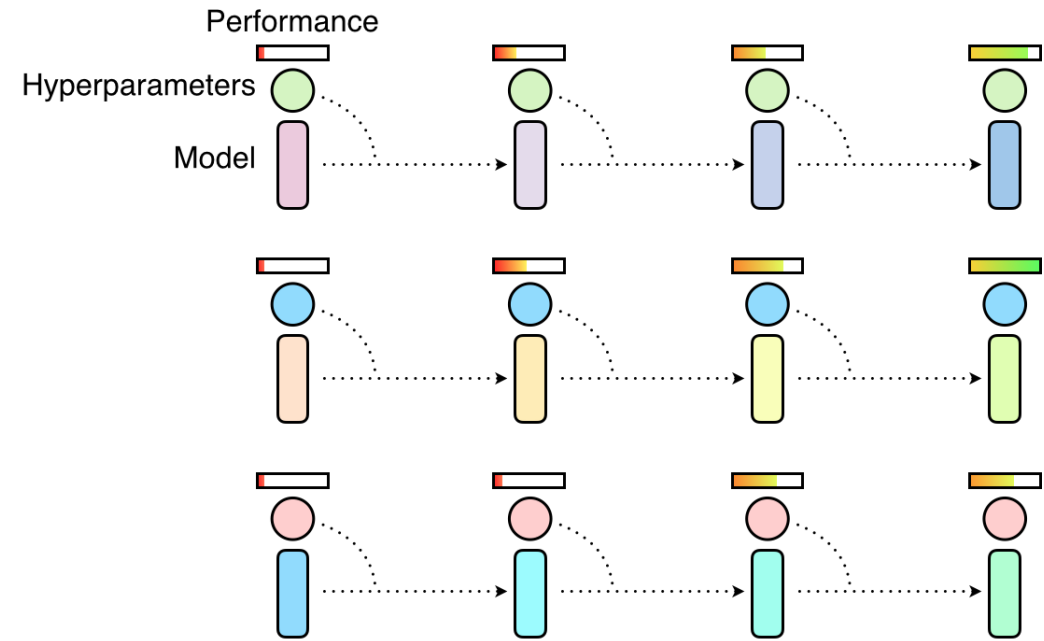

Our Contribution: Hyperparameters Approach

(a) Sequential Optimisation

(b) Parallel Random/Grid Search

(c) Population Based Training
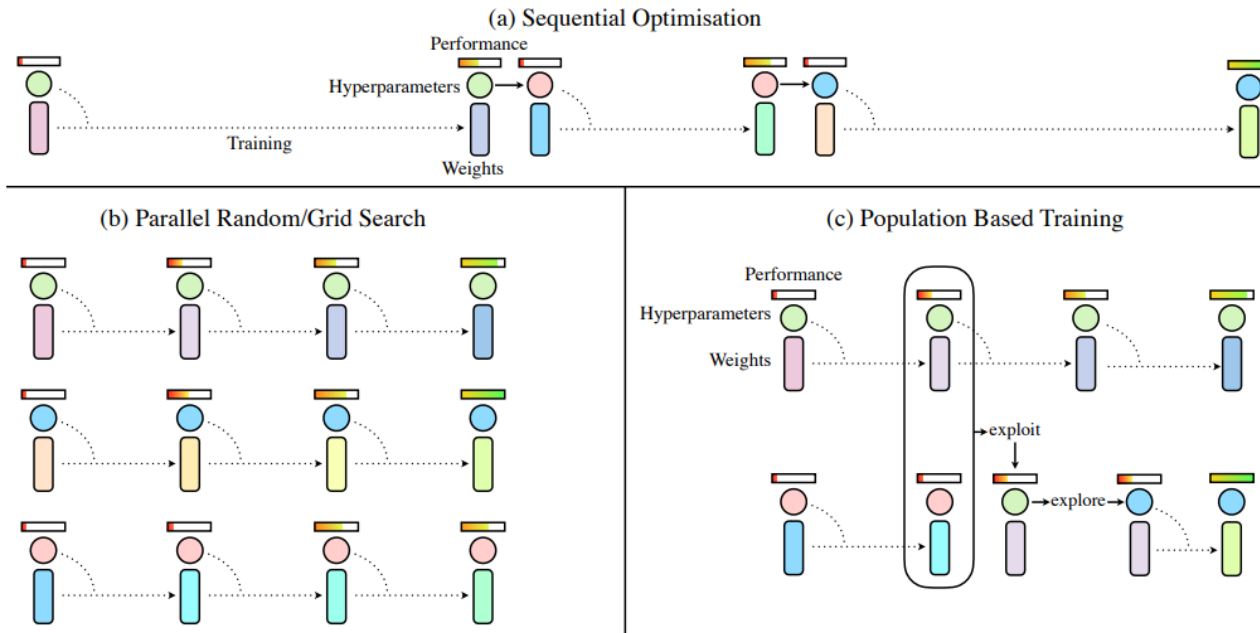

- Better understanding of PBT-based training mechanisms using distributed computational architectures
- Framework that implements efficient and scalable PBT mechanisms that, through evolutionary algorithms, allows finding generalizable models that minimize memory consumption.
- PBT techniques allow obtaining more optimal generalized models that consume less memory,.

Quantum Processor Unit Architecture*
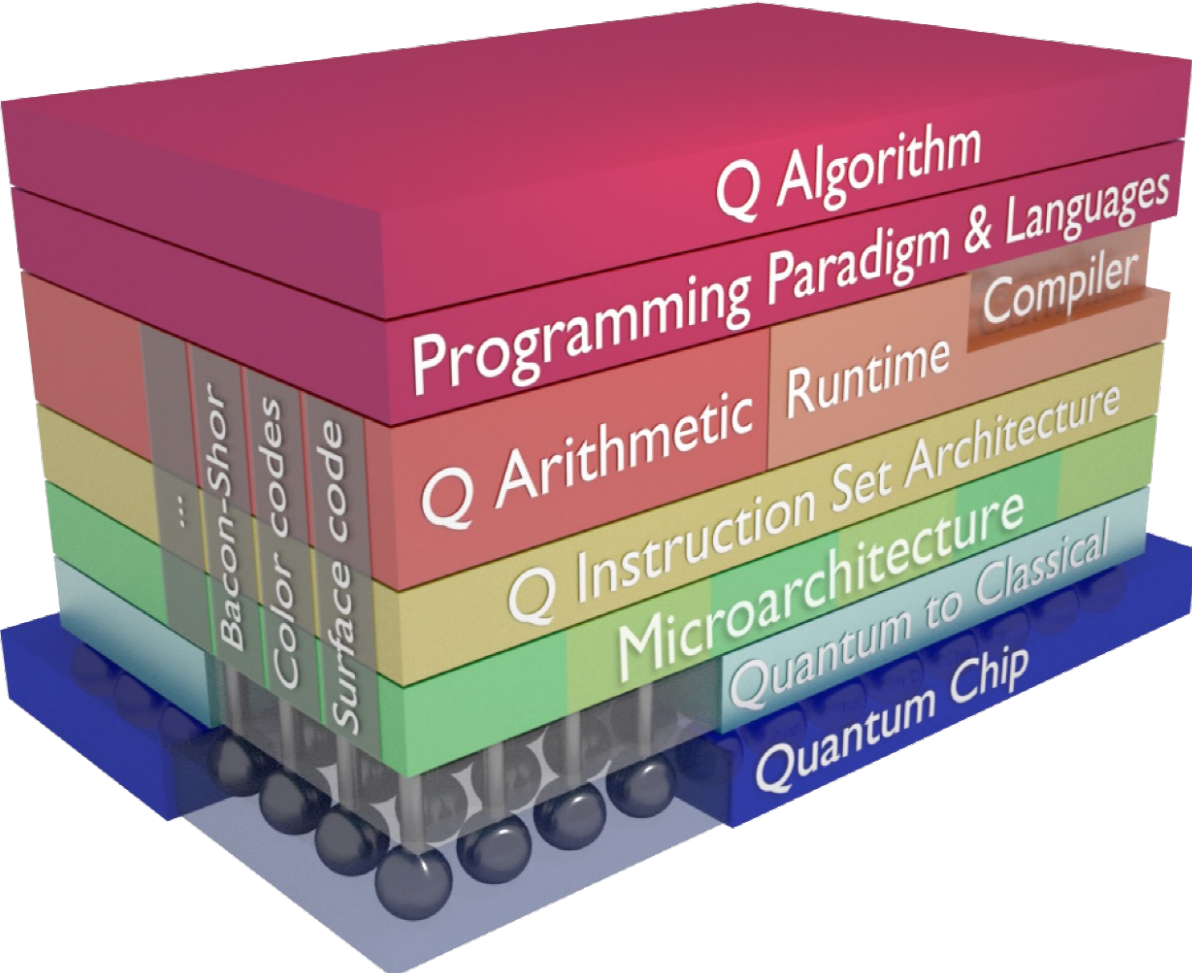

*Simplest Approach
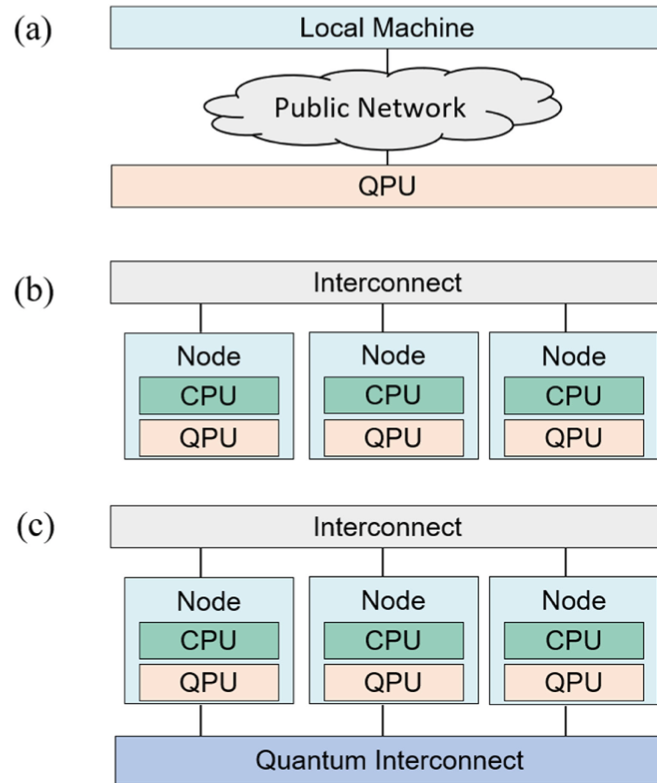

Quantum Computing Over HPC

FIGURE 2. Three macroarchitectures for integrating quantum computing with conventional computing. (a) A local machine remotely accesses a QPU through public cloud network. (b) A network of quantum-accelerated nodes communicate through a common interconnect. (c) A network of quantum-accelerated nodes communicate through both conventional and quantum networks.

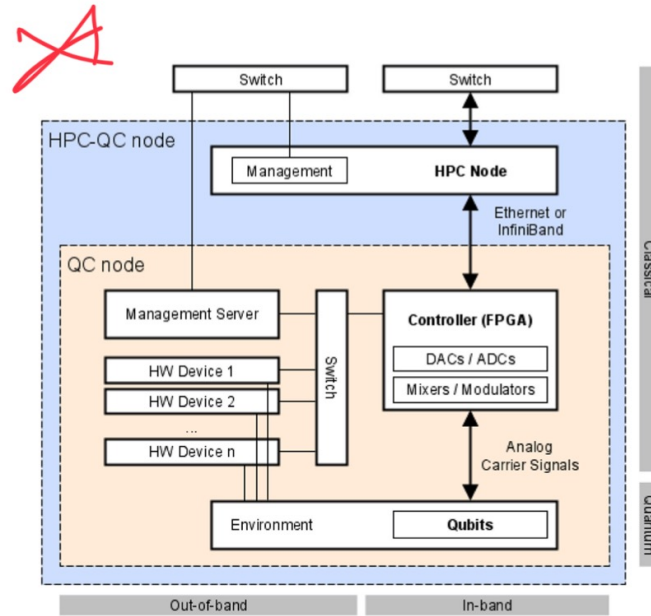

FIGURE 3. A component diagram representing the microarchitecture of a HPC-QC node with a common interconnect as depicted in Figure 2(b). The diagram shows the major components needed for the operation of a QPU within the HPC node infrastructure. Individual components are grouped into so-called out-of-band and in-band scopes and are placed on the left-hand and right-hand side of the figure, respectively. The QPU, which contains the qubits and is capable of processing quantum information, is depicted at the lower part, whereas classical information processing components are shown in the upper part of the figure. Several hardware (HW) devices control the QPU environment, which has a direct effect on qubit properties and thus the quality of execution of instructions.

DEPARTMENT: EXPERT OPINION

Quantum Computers for High-Performance Computing

Travis S. Humble, Alexander McCaskey, Dmitry I. Lyakh, and Meenambika Gowrishankar, *Quantum Computing Institute, Oak Ridge National Laboratory, Oak Ridge, TN, 37830, USA*
Albert Frisch, *Alpine Quantum Technologies, Innsbruck, 6020, Austria*
Thomas Monz, *Alpine Quantum Technologies, Innsbruck, 6020, Austria and also Institut für Experimentalphysik, Universität Innsbruck, Innsbruck, 6020, Austria*

Quantum computing systems are developing rapidly as powerful solvers for a variety of real-world calculations. Traditionally, many of these same applications are solved using conventional high-performance computing (HPC) systems, which have progressed sharply through decades of hardware and software improvements. Here, we present a perspective on the motivations and challenges of pairing quantum computing systems with modern HPC infrastructure. We outline considerations and requirements for the use cases, macroarchitecture, microarchitecture, and programming models needed to integrate near-term quantum computers with HPC system, and we conclude with the expectation that such efforts are well within reach of current technology.

High-performance computing (HPC) systems define the pinnacle of modern computing by drawing on massively parallel processing. This leading paradigm for HPC often relies on specialized accelerators and highly tuned networks to optimize data movement and application performance, whereby many computational nodes are connected by high-bandwidth networks to support shared information processing tasks. Existing computational nodes also support highly concurrent execution with multi-threaded processing, and technology trends indicate that future node designs will integrate heterogeneous processing paradigms that include conventional central processing units (CPUs), graphics processing units (GPUs), field-programmable gate arrays (FPGAs), and other specialized processors.[1] The components of these future computational nodes must be tightly integrated to balance data movement with processing power and workload in order to optimize overall system performance.

By comparison, quantum computers (QCs) represent a young yet remarkable advance in the science and technology of computation that are often cited as rivals or successors to state-of-the-art conventional high-performance computing (HPC) systems. The source of this proposed advantage of QCs derives from quantum information processing in which information is encoded in the quantum state of physical systems such as atoms, electrons, and photons.[2] These quantum physical systems present the unique features of quantum coherence and quantum entanglement that permit quantum computing to reduce exponentially the computational time and memory needed to solve many problems from chemistry, materials science, finance, and cryptanalysis among other application domains. The advantage afforded to quantum computing is therefore aptly named the "quantum computational advantage," and there is now a fervent effort to realize quantum computing systems that demonstrate this advantage. Notably, recent efforts have focused on besting the world's leading HPC systems to great effect.[3,4,5]

Many of the most promising applications of quantum computing overlap strongly with existing applications of HPC,[6] which begs the question of how QCs may be integrated with modern HPC to accelerate these

35

Open Question 4: And Quantum Computing?

Our Contribution: Quantum Computing Theory for Quantum Computing Applications
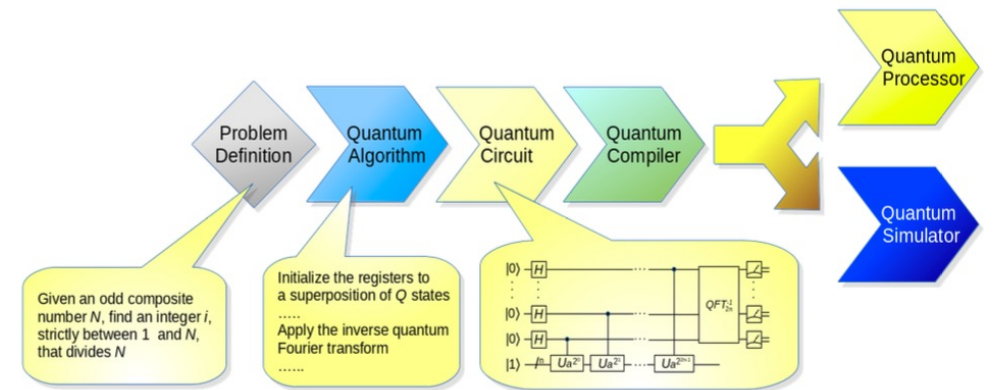

The term **quantum algorithm** is generally used for those algorithms that incorporate some essential feature of **quantum computing**, such as superposition or entanglement. By using this special features, we can speed up significantly the calculation, that is called **quantum parallelism**.
